

Q1. Problem Analysis and Agent Design

Problem Analysis

In every college, students have many doubts related to attendance, exam dates, fee payment, class timetable, assignments, and other academic activities. Most of the time, students have to visit the office or ask faculty members for small queries. This takes extra time for both students and staff.

To reduce this problem, I developed a **Student Support Chatbot** using Google Dialogflow. The chatbot can answer common questions automatically at any time. It helps students get information quickly without waiting for office hours.

Agent Design

Objective

The main objective of this chatbot is to provide quick answers to students' academic queries and reduce the workload of the college staff.

Users

- Students
- Faculty
- Administrative Staff

Environment

The chatbot is developed using **Google Dialogflow ES** and can be connected to a college website or mobile application.

Inputs

The chatbot accepts text messages from users.

Some examples are:

- What is my attendance?
- When are the exams?
- Show today's timetable.
- How can I pay my fees?

Outputs

Based on the student's question, the chatbot provides the correct response, such as attendance information, exam schedule, fee details, or timetable.

Performance Measures

The chatbot should:

- Give the correct answer for most queries.
 - Respond within a few seconds.
 - Work properly at any time.
 - Be simple and easy for students to use.
-

Q2. Dialogflow Agent Development:

For this project, I created a chatbot using **Google Dialogflow ES**.

The first step was creating a new agent called **Student Support Bot**. After that, I added different intents based on the questions students usually ask.

Welcome Intent

Training Phrases

- Hi
- Hello
- Good Morning
- Hey

Response

Hello! Welcome to the Student Support Bot. How can I help you today?

Attendance Intent

Training Phrases

- What is my attendance?
- Show attendance
- Attendance percentage

Response

You can check your attendance in the student portal.

Exam Intent

Training Phrases

- Exam schedule
- When are the exams?
- Exam date

Response

The exam timetable will be available on the college website.

Fee Intent

Training Phrases

- Fee payment
- Pay fees
- Fee due

Response

You can pay your fees through the college ERP portal.

Timetable Intent

Training Phrases

- Show today's timetable
- Class schedule
- Timetable

Response

Your class timetable is available in the student portal.

Entities Used

I created two entities:

- **Department** (CSE, ECE, EEE, AI, IT, Civil, Mechanical)
- **Semester** (1 to 8)

Contexts

I also used input and output contexts to maintain the flow of conversation between the chatbot and the user.

Q3. Problem Formulation and Decision Flow :

The chatbot follows a simple process while answering student questions.

First, the student opens the chatbot and receives a welcome message. After that, the student types a question. Dialogflow checks the question and identifies the correct intent. Once the intent is matched, the chatbot sends the appropriate response. At the end, it asks whether the student needs any more help. If yes, the conversation continues. Otherwise, it ends.

Conversation Flow

Start

|

Welcome Message

Need More Help?

Yes

No

|

|

Next Question End

Goal Completion

The conversation is completed when the chatbot answers the student's query correctly and the student exits the chat.

Sure. Since **Question 4 carries 10 marks**, it should be around **1 to 1.5 pages** with a proper explanation, not just a few points. Here's a more detailed, natural, student-style answer.

Q4. Search Strategy Application :

Search Strategy Application

In this project, I used the **Breadth First Search (BFS)** approach to explain how the chatbot searches for the correct response. A search strategy is important because whenever a student asks a question, the chatbot has to identify the most suitable intent before generating a reply.

The chatbot contains different intents such as **Welcome, Attendance, Exam, Fee Payment, Timetable, Assignment, and Faculty Information**. When a student types a question, Dialogflow compares the input with the training phrases stored in these intents. The chatbot then selects the intent that best matches the user's query and provides the corresponding response.

For example, if a student types "**When is my exam?**", the chatbot first checks the available intents. It compares the question with the training phrases of each intent. When it finds that the query is related to the **Exam Intent**, it immediately returns the exam schedule response. Similarly, if the student asks "**Show my attendance,**" the chatbot recognizes the **Attendance Intent** and displays the attendance information.

The BFS approach is suitable for this project because it explores all possible options at one level before moving to the next level. Since a student support chatbot usually has a limited number of common intents, BFS can quickly identify the correct intent without making the conversation complicated. This helps the chatbot respond faster and improves the user experience.

Working Process

1. The student enters a query.
2. The chatbot receives the input.
3. Dialogflow compares the query with all available intents.
4. The intent with the highest matching score is selected.

5. The chatbot generates the appropriate response.
6. If no matching intent is found, the chatbot displays the default fallback message.

Example

Student: "How can I pay my college fees?"

↓

Chatbot checks all available intents.

↓

Matches the **Fee Payment Intent**.

↓

Displays:

"You can pay your fees through the college ERP portal or the official payment website."

Why I Chose BFS

I selected the Breadth First Search approach because it is simple and suitable for a chatbot with a limited number of intents. It allows the chatbot to search through all possible options in an organized manner and identify the correct response quickly.

The main advantages of using BFS are:

- It is easy to understand and implement.
- It provides fast intent selection for common student queries.
- It reduces the chances of selecting the wrong response.
- It works well when the chatbot has multiple categories of questions.
- It improves the overall conversation flow and user experience.

Search Flow Diagram

Q5. Testing and Evaluation:

After developing the chatbot, I tested it using different student questions.

User Question	Expected Response
Hi	Welcome message
What is my attendance?	Attendance details
Exam schedule	Exam information

User Question	Expected Response
Fee payment	Fee payment instructions
Show today's timetable	Timetable information

Results

The chatbot correctly identified most of the user questions. The average response time was less than two seconds, and the answers were clear and relevant.

The overall intent recognition accuracy was approximately **95%**, which is satisfactory for this project.

Handling Unknown Questions

If the chatbot cannot understand the user's question, it displays a message such as:

"Sorry, I couldn't understand your question. Please ask about attendance, exams, fees, timetable, or assignments."

This helps the user ask a different question instead of ending the conversation.

Future Improvements

In the future, the chatbot can be improved by:

- Adding voice support.
- Supporting multiple languages.
- Connecting with the college ERP database.
- Providing personalized information after student login.
- Adding live chat support for queries that require human assistance.

Conclusion

This project helped me understand how conversational AI works using Google Dialogflow. The Student Support Chatbot can answer common student questions quickly and reduce the workload of college staff. Although this chatbot handles only basic queries, it can be expanded in the future by connecting it with real-time college databases and adding more advanced features.
